Illumination number of the unconditionally symmetric 4-dimensional cap body of a ball

Cap body of a ball in $\mathbb{E}^d$ (as introduced by Minkowski in 1903) is a convex hull of an origin centered euclidean closed unit ball $B^d(o)$ and a countable set of points outside of the ball $\{p_1, p_2, \ldots\} \in \mathbb{E}^d \setminus B^d(o)$ such that for any two points $p_i, p_j$ the segment $[p_i, p_j]$ has a nonempty intersection with $B^d(o)$.

Unconditionally symmetric convex body in $\mathbb{E}^d$ is a body that together with every its point with coordinates $(x_1, \ldots, x_d)$ also contains all the points with coordinates $(\pm x_1, \ldots, \pm x_d)$. In my talk I will show that 8 illumination directions are enough to completely illuminate the boundary of an unconditionally symmetric cap body of a ball in $\mathbb{E}^d$.
