The CMS is pleased to offer free access to its back file of all issues of Crux as a service for the greater mathematical community in Canada and beyond.

Journal title history:

- The first 32 issues, from Vol. 1, No. 1 (March 1975) to Vol. 4, No.2 (February 1978) were published under the name EUREKA.
- Issues from Vol. 4, No. 3 (March 1978) to Vol. 22, No. 8 (December 1996) were published under the name Crux Mathematicorum.
- Issues from Vol 23., No. 1 (February 1997) to Vol. 37, No. 8 (December 2011) were published under the name Crux Mathematicorum with Mathematical Mayhem.
- Issues since Vol. 38, No. 1 (January 2012) are published under the name Crux Mathematicorum.
The support of the University of Calgary Department of Mathematics and Statistics is gratefully acknowledged.

CRUX MATHEMATICORUM is a problem-solving journal at the senior secondary and university undergraduate levels for those who practise or teach mathematics. Its purpose is primarily educational, but it serves also those who read it for professional, cultural, or recreational reasons.

It is published monthly (except July and August). The yearly subscription rate for ten issues is $22.50 for members of the Canadian Mathematical Society and $25 for nonmembers. Back issues: $2.75 each. Bound volumes with index: Vols. 1 & 2 (combined) and each of Vols. 3-10: $20. All prices quoted are in Canadian dollars. Cheques and money orders, payable to CRUX MATHEMATICORUM, should be sent to the Managing Editor.

All communications about the content of the journal should be sent to the Editor. All changes of address and inquiries about subscriptions and back issues should be sent to the Managing Editor.

Founding Editors: Léo Sauvé, Frederick G.B. Maskell.

Editor: G.W. Sands, Department of Mathematics and Statistics, University of Calgary, 2500 University Drive N.W., Calgary, Alberta, Canada, T2N 1N4.

Managing Editor: Dr. Kenneth S. Williams, Canadian Mathematical Society, 577 King Edward Avenue, Ottawa, Ontario, Canada, K1N 6N5.

ISSN 0705 - 0348.

THE OLYMPIAD CORNER: 76

M.S. KLAMKIN

All communications about this column should be sent to M.S. Klamkin, Department of Mathematics, University of Alberta, Edmonton, Alberta, Canada, T6G 2G1.

This month I give the problems of the 1986 Canadian Mathematical Olympiad (received through secondary sources) and the 1986 U.S.A. Mathematical Olympiad by courtesy of Walter Mientka. The U.S.A.M.O. was set by J. Konhauser, A. Liu, G. Patruno, and I. Richards (chairman).

EIGHTEENTH CANADIAN MATHEMATICS OLYMPIAD (1986)
Wednesday, May 7, 1986 9:00 a.m. - 12:00 noon

1. In the diagram AB and CD are of length 1 while angles ABC and CBD are 90° and 30° respectively. Find AC.

2. A Mathlon is a competition in which there are M athletic events.

Such a competition was held in which only A, B and C participated. In each event \( p_1 \) points were awarded for first place, \( p_2 \) for second and \( p_3 \) for third where \( p_1 > p_2 > p_3 > 0 \) and \( p_1, p_2, p_3 \) are integers. The final score for A was 22, for B was 9 and for C was also 9. B won the 100 metres. What is the value of \( M \) and who was second in the high jump?

3. A chord ST of constant length slides around a semicircle with diameter AB. M is the mid-point of ST and P is the foot of the perpendicular from S to AB. Prove that angle SPM is constant for all positions of ST.

4. For positive integers \( n \) and \( k \), define \( F(n,k) = \Sigma_{r=1}^{n} r^{2k-1} \). Prove that \( F(n,1) \) divides \( F(n,k) \).
5. Let \( u_1, u_2, u_3, \ldots \) be a sequence of integers satisfying the recurrence relation \( u_{n+2} = u_{n+1}^2 - u_n \). Suppose \( u_1 = 39 \) and \( u_2 = 45 \). Prove that 1986 divides infinitely many terms of the sequence.

THE FIFTEENTH U.S.A. MATHEMATICAL OLYMPIAD
April 22, 1986

1. **Part a.** Do there exist 14 consecutive positive integers each of which is divisible by one or more primes \( p \) from the interval \( 2 \leq p \leq 11 \)?

2. **Part b.** Do there exist 21 consecutive positive integers each of which is divisible by one or more primes \( p \) from the interval \( 2 \leq p \leq 13 \)?

2. During a certain lecture, each of five mathematicians fell asleep exactly twice. For each pair of these mathematicians, there was some moment when both were sleeping simultaneously. Prove that, at some moment, some three of them were sleeping simultaneously.

3. What is the smallest integer \( n \), greater than one, for which the root-mean-square of the first \( n \) positive integers is an integer?

Note: The root-mean-square of \( n \) numbers \( a_1, \ldots, a_n \) is defined to be

\[
\left( \frac{a_1^2 + \ldots + a_n^2}{n} \right)^{1/2}.
\]

4. Two distinct circles \( K_1 \) and \( K_2 \) are drawn in the plane. They intersect at points \( A \) and \( B \), where \( AB \) is a diameter of \( K_1 \). A point \( P \) on \( K_2 \) and inside of \( K_1 \) is also given.

Using only a "T-square" (i.e. an instrument which can produce the straight line joining two points and the perpendicular to a line through a point on or off the line), find an explicit construction for:

- two points \( C \) and \( D \) on \( K_1 \) such that \( CD \) is perpendicular to \( AB \) and \( CPD \) is a right angle.

5. By a partition \( \pi \) of an integer \( n \geq 1 \), we mean a representation of \( n \) as a sum of one or more positive integers, where the summands must be put in nondecreasing order. (E.g. if \( n = 4 \), then the partitions \( \pi \) are \( 1 + 1 + 1 + 1, 1 + 1 + 2, 1 + 3, 2 + 2, \) and \( 4 \).)

For any partition \( \pi \), define \( A(\pi) \) to be the number of 1's which appear in \( \pi \), and define \( B(\pi) \) to be the number of distinct integers which appear in \( \pi \). (E.g. if \( n = 13 \) and \( \pi \) is the partition \( 1 + 1 + 2 + 2 + 2 + 5 \), then \( A(\pi) = 2 \) and \( B(\pi) = 3 \).)
Prove that, for any fixed $n$, the sum of $A(\pi)$ over all partitions $\pi$ of $n$ is equal to the sum of $B(\pi)$ over all partitions $\pi$ of $n$.

I now give solutions to some problems from Corner 62 [1985: 36].

1. Proposed by Australia.

A total of 1983 cities are served by ten airlines. There is direct service (without stopovers) between any two cities and all airline schedules run both ways. Prove that at least one of the airlines can offer a round trip with an odd number of landings.

Solution.

More generally, suppose there are $n$ airlines $A_1, A_2, \ldots, A_n$ and $m$ cities $C_1, C_2, \ldots, C_m$ with $m > 2^n$. We will show that there is at least one airline $A_i$ having a round trip with an odd number of landings. For $n = 1$, the result is immediate since the one airline must serve at least 3 cities and $C_1 C_2 C_3 C_1$ is a round trip with 3 landings. We now use induction and assume the result is valid for $n - 1$ airlines for $n > 1$. We can assume that all the round trips by $A_n$ consist of an even number of landings, otherwise our proof is done. Now we can separate the cities served by $A_n$ into the two non-empty classes $\{D_1, D_2, \ldots, D_r\}$ and $\{E_1, E_2, \ldots, E_s\}$ where $r + s = m$, so that each flight by $A_n$ flies only between a $D$-city and an $E$-city. [For a proof of this, consider any city, say $D_1$. Call each city linked by $A_n$ to $D_1$ an $E$-city, call all the cities linked by $A_n$ to any of these $E$-cities a $D$-city, etc. If any cities remain, pick one and call it a $D$-city. Call each city linked to it by $A_n$ an $E$-city, etc. Continue until all cities have been considered. No contradiction can arise since all the round trips have an even number of landings.] Since $r + s = m > 2^n$, at least one of $r$, $s$, say $r$, is greater than $2^{n-1}$. But the cities $D_1, D_2, \ldots, D_r$ are linked only by the $n-1$ airlines $A_1, A_2, \ldots, A_{n-1}$, and hence by the inductive hypothesis at least one of them offers a round trip with an odd number of landings. For the original problem, we only have to note that $2^{10} = 1024 < 1983$.

To show that the above general result is sharp, we give a schedule for $m = 2^n$ cities for which there are no round trips with an odd number of
landings. Let the cities be $F_k$ where $k = 0, 1, \ldots, 2^n - 1$. We now write each such $k$ as an $n$-digit binary number (possibly starting with a number of zero digits). We link $F_i$ and $F_j$ with $A_1$ if the first digits of $i$ and $j$ are distinct, with $A_2$ if the first digits are the same but the second digits are different, \ldots, with $A_n$ if the first $n - 1$ digits are the same but the last ($n^{th}$) digits are different. Then for any $i$, all round trips by $A_i$ have an even number of landings since the $i^{th}$ digit alternates.

The altitude from a vertex of a given tetrahedron intersects the opposite face in its orthocenter. Prove that all four altitudes of the tetrahedron are concurrent.

Solution.

Let $PABC$ be the tetrahedron and $H$ be the foot of the altitude from $P$. Since $AH$ and $PH$ are orthogonal to $BC$, so also is $AP$. Similarly, $ABLP$ and $ACPB$. A tetrahedron whose opposite sides are orthogonal in pairs is said to be orthocentric. It is a known result (see p.71 of N. Altshiller-Court, Modern Pure Solid Geometry, Chelsea, New York, 1964, for a synthetic proof) that the four altitudes of an orthocentric tetrahedron are concurrent.

For practice in vector geometry, give a vector solution of the above problem.

3. Proposed by Brazil.

Which of the numbers 1, 2, \ldots, 1983 have the largest number of positive divisors?

Solution.

The divisors of a number $n$ with prime decomposition

$$p_1^{a_1} p_2^{a_2} \cdots p_m^{a_m}$$

are all the terms of the product expansion of

$$(1 + p_1 + \cdots + p_1^{a_1})(1 + p_2 + \cdots + p_2^{a_2}) \cdots (1 + p_m + \cdots + p_m^{a_m}).$$

Consequently, the number of its positive divisors $N(n)$ is given by

$$(1 + a_1)(1 + a_2) \cdots (1 + a_m).$$

Since this number only depends on the exponents $a_i$ and not the prime factors, it will be maximized for a given $m$ if the primes $p_1, \ldots, p_m$ are chosen to be the first $m$ primes. Thus we need only
consider numbers of the form $2^a$, $2^a3^b$, $2^a3^b5^c$, and $2^a3^b5^c7^d$ since $2·3·5·7·11 > 1983$. Moreover, it is easy to see we may assume $a > b > c > d$. With a little trial and error, we find the maximum $N(n)$ for each of the latter forms are:

$$N(2^{10}) = 11, \quad N(2^6·3^3) = 28, \quad N(2^3·3^2·5^2) = N(2^5·3^2·5) = 36,$$

$$N(2^4·3·5·7) = 40.$$  
Hence $2^4·3·5·7 = 1680$ has the largest number of divisors.

4. **Proposed by Canada.**

Find all possible finite sequences $\{n_0, n_1, \ldots, n_k\}$ of integers such that, for each $i = 0, 1, \ldots, k$, $i$ appears in the sequence $n_i$ times.

**Editorial note:** Such sequences are called self-descriptive strings and are treated in the following two papers:

It is shown in [1] that for $k > 6$, a self-descriptive string exists and is unique, and is given by the second row of the table

<table>
<thead>
<tr>
<th>Number (i)</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>k-4</th>
<th>k-3</th>
<th>k-2</th>
<th>k-1</th>
<th>k</th>
</tr>
</thead>
<tbody>
<tr>
<td>Occurrence (n_i)</td>
<td>k-3</td>
<td>2</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>...</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The only self-descriptive strings for $k < 6$ are {1,2,1,0}, {2,0,2,0}, and {2,1,2,0,0}. For a related paper, see L. Sallows and V.L. Eijkhout, Co-descriptive strings, *Math. Gazette* 70 (1986) 1-10.

5. **Proposed by Canada.**

Let $a_0 = 0$ and

$$a_{n+1} = k(a_n + 1) + (k+1)a_n + 2k(k+1)a_n(a_n + 1), \quad n = 0, 1, 2, \ldots,$$

where $k$ is a positive integer. Prove that $a_n$ is a positive integer for $n = 1, 2, 3, \ldots$.

**Solution.**

Since $a_0 = 0$, $a_1 = k$. We solve the given recurrence equation for $a_n$ in terms of $a_{n+1}$:
\[ a_{n+1} - (2k+1)a_n - k = 2\sqrt{k(k+1)}a_{n+1}(a_{n+1}+1) \]
\[ a_{n+1}^2 + (2k+1)^2a_n^2 + k^2 = 2(2k+1)a_{n+1}a_n - 2ka_{n+1}^2 + 2k(2k+1)a_n \]
\[ = 4k(k+1)(a_{n+1}^2 + a_n^2) \]
\[ a_{n+1}^2 - 2ka_n - 2(2k+1)a_{n+1}a_n + (a_{n+1} - k)^2 = 0 \]

So
\[ a_n = \frac{2k + 2(2k+1)a_{n+1} \pm \sqrt{4[k(2k+1)a_{n+1}^2 - 4(a_{n+1} - k)^2]}}{2} \]
\[ = k + (2k+1)a_{n+1} \pm \sqrt{(4k^2+4k)a_{n+1}^2 + (4k^2+4k)a_{n+1}} \]
\[ = k(a_{n+1} + 1) + (k+1)a_{n+1} - 2\sqrt{k(k+1)a_{n+1}(a_{n+1}+1)} \]

since \( a_n < a_{n+1} \). We now add this equation to the given equation with \( n \) replaced by \( n + 1 \) to give
\[ a_n + a_{n+2} = 2k(a_{n+1} + 1) + 2(k+1)a_{n+1} \]
or
\[ a_{n+2} = (4k+2)a_{n+1} - a_n + 2k. \]

It now follows by induction that \( a_n \) is a positive integer for \( n = 2, 3, 4, \ldots \).

For extensions of this result see M.S. Klamkin, Perfect squares of the form \((m^2-1)a_n^2 + t\), Math. Mag. 42 (1969) 111-113.

6. Proposed by Cuba.

Show that there exist infinitely many sets of 1983 consecutive positive integers each of which is divisible by some number of the form \( a^{1983} \), where \( a \neq 1 \) is a positive integer.

Solution by Curtis Cooper, Central Missouri State University, Warrensburg, Missouri.

The following proof is due to S.M. Akers Jr. (solution III to problem 106, Math. Mag. 25 (1952) 222; reprinted in R. Honsberger, Mathematical Morsels, M.A.A., 1978, pp.136-137). It shows by induction on \( n \) that for any integer \( m \geq 1 \) there exists a set of \( n \) consecutive natural numbers each of which is divisible by a number of the form \( a^m \), where \( a \neq 1 \) is a positive integer.

(i) For \( n = 1 \), \( a^m \) for any integer \( a > 1 \) satisfies the requirement.

(ii) Suppose for \( n \geq 1 \), the \( n \) consecutive natural numbers \( A_1, A_2, \ldots, A_n \) are each divisible by an \( m^{th} \) power \( > 1 \). Now we look for \( n + 1 \) consecutive
numbers with the same property. Let
\[ a_1^m, a_2^m, \ldots, a_n^m > 1 \]
divide
\[ A_1, A_2, \ldots, A_n, \]
respectively, and let \( L = a_1^m a_2^m \ldots a_n^m \). Next let \( A_{n+1} = A_n + 1 \) and
\[ A = A_{n+1} [ (L+1)^m - 1 ] . \]
Then
\[ A + A_1, A + A_2, \ldots, A + A_{n+1} \]
are \( n + 1 \) consecutive numbers divisible by
\[ a_1^m, a_2^m, \ldots, a_n^m, (L+1)^m \]
respectively. Thus the result is true by induction.

7. \textit{Proposed by Finland.}

Let \( r \) and \( s \) be integers, with \( s > 0 \). Show that there exists an interval \( I \) of length \( 1/s \) and a polynomial \( P(x) \) with integral coefficients such that, for all \( x \in I \),
\[ |P(x) - r/s| < 1/s^2. \]

\textbf{Solution.}

Let \( n \) be a positive integer and \( P(x) = r(1 - (sx-1)^{2n})/s, \frac{1}{2s} \leq x \leq \frac{3}{2s} \). Then \( |sx-1| \leq \frac{1}{2s} \). Clearly, \( P(x) \) is an integral polynomial and
\[ |P(x) - r/s| = \left| \frac{r}{s} (sx-1)^{2n} \right| \leq \left| \frac{r}{s} \right| 2^{-2n}. \]
Finally, we can choose \( n \) sufficiently large so that \( \left| \frac{r}{s} \right| 2^{-2n} < \frac{1}{s^2} \). (Just take \( 2n > \log_2 |rs| \)).

\* \* \*
PROBLEMS

Problem proposals and solutions should be sent to the editor, whose address appears on the front page of this issue. Proposals should, whenever possible, be accompanied by a solution, references, and other insights which are likely to be of help to the editor. An asterisk (*) after a number indicates a problem submitted without a solution.

Original problems are particularly sought. But other interesting problems may also be acceptable provided they are not too well known and references are given as to their provenance. Ordinarily, if the originator of a problem can be located, it should not be submitted by somebody else without his or her permission.

To facilitate their consideration, your solutions, typewritten or neatly handwritten on signed, separate sheets, should preferably be mailed to the editor before January 1, 1987, although solutions received after that date will also be considered until the time when a solution is published.

Disjoint, non-touching spheres \( O_1 \) and \( O_2 \) are inside and tangent to a sphere \( O \). Four spheres \( S_1, S_2, S_3, S_4 \), each tangent to two of the others as well as to \( O_1, O_2, \) and \( O \), are packed in a ring in that order inside \( O \) and around \( O_1 \) and \( O_2 \). Show that

\[
\frac{1}{r_1} + \frac{1}{r_3} = \frac{1}{r_2} + \frac{1}{r_4}
\]

where \( r_i \) is the radius of \( S_i \).

1151. Proposed by Jack Garfunkel, Flushing, N.Y.

Prove (or disprove) that for an obtuse triangle \( ABC \),

\[
m_a + m_b + m_c \leq s\sqrt{3}
\]

where \( m_a, m_b, m_c \) denote the medians to sides \( a, b, c \) and \( s \) denotes the semiperimeter of \( \triangle ABC \). Equality is attained in the equilateral triangle.

Prove that

\[
\Sigma \cos \frac{\alpha}{2} \leq \frac{\sqrt{3}}{2} \Sigma \cos \frac{1}{4}(\beta - \gamma)
\]

where \( \alpha, \beta, \gamma \) are the angles of a triangle and the sums are cyclic over these angles.
1153. Proposed by Richard K. Guy, University of Calgary, Calgary, Alberta.

The answers are distinct 2- and 3-digit decimal numbers, none beginning with zero. Each of the above sets of answers is a primitive Pythagorean triple, in increasing size, so that the third member is the hypotenuse. A = across, B = back, D = down, U = up. For example, 1B has its tens & units digits in the squares labelled 2 & 1 respectively; 11U is a 3-digit number with its tens & units digits in squares 16 & 11 respectively.

1154. Proposed by Walther Janous, Ursulinengymnasium, Innsbruck, Austria.

Let $A$, $B$, and $C$ be the angles of an arbitrary triangle. Determine the best lower and upper bounds of the function

$$f(A,B,C) = \sum \sin^{2} - \sum \sin^{2} \sin$$

(where the summations are cyclic over $A$, $B$, $C$) and decide whether they are attained.
1155. Proposed by Roger Izard, Dallas, Texas.

In triangle $ABC$ cevians $AD$, $BE$, and $CF$ meet at point $O$. Points $F$, $B$, $C$, and $E$ are concyclic. Points $A$, $F$, $D$, and $C$ are also concyclic. Show that $AD$, $BE$, and $CF$ are altitudes.

1156. Proposed by Hideosi Fukagawa, Yokosuka High School, Aichi, Japan.

At any point $P$ of an ellipse with semiaxes $a$ and $b$ ($a > b$), draw a normal line and let $Q$ be the other meeting point. Find the least value of length $PQ$, in terms of $a$ and $b$.

Find all triples of positive integers $(r,s,t)$, $r < s$, $t$, for which $(rs + r + 1)(st + s + 1)(tr + t + 1)$ is divisible by $(rst - 1)^2$. This problem was suggested by Routh's Theorem (see Crux [1981: 199]).

1158. Proposed by Svetoslav Bilchev, Technical University, Russe, Bulgaria.

Prove that

$$
\sum \frac{1}{(\sqrt{2} + 1)\cos A - \sin A} \geq \frac{\sqrt{2}}{3 - \sqrt{2}}
$$

where the sum is cyclic over the angles $A$, $B$, $C$ of a triangle. When does equality occur?

1159. Proposed by George Tsintsifas, Thessaloniki, Greece.

Let $ABC$ be a triangle and $P$ some interior point with distances $AP = x_1$, $BP = x_2$, $CP = x_3$. Show that

$$(b + c)x_1 + (c + a)x_2 + (a + b)x_3 \geq 8F,$$

where $a$, $b$, $c$ are the sides of $\triangle ABC$ and $F$ is its area.

1160. Proposed by Clark Kimberling, University of Evansville, Evansville, Indiana.

Let $A'$, $B'$, $C'$ be the first points of intersection of the angle bisectors of a triangle $ABC$ with its incircle $I$. The tangents to $I$ at $A'$, $B'$, $C'$ form a triangle $A'B'C'$. Prove that the lines $AA'$, $BB'$, $CC'$ are concurrent.

*  

*  

*
SOLUTIONS

No problem is ever permanently closed. The editor will always be pleased to consider for publication new solutions or new insights on past problems.

If \( \lambda > \mu \) and \( a \geq b \geq c > 0 \), prove that

\[
\frac{2\lambda}{c} 2\mu + \frac{2\lambda}{a} 2\mu + \frac{2\lambda}{b} 2\mu \geq (bc)^{\lambda+\mu} + (ca)^{\lambda+\mu} + (ab)^{\lambda+\mu}
\]

with equality just when \( a = b = c \).

Further generalizations by M.S. Klamkin, University of Alberta, Edmonton, Alberta.

I. First we show that if \( a_1 \geq a_2 \geq \ldots \geq a_n > 0 \) and either \( \lambda > \mu > 0 \) or \( 0 > \lambda > \mu \), then

\[
\frac{2\lambda}{a_1} a_2 + \frac{2\lambda}{a_2} a_3 + \ldots + \frac{2\lambda}{a_n} a_1 \geq (a_1 a_2)^{\lambda+\mu} + (a_2 a_3)^{\lambda+\mu} + \ldots + (a_n a_1)^{\lambda+\mu}
\]

(1)

with equality if and only if \( a_1 = a_2 = \ldots = a_n \).

From inequality (6) on [1980: 107], we have that if \( x_1 \geq x_2 \geq \ldots \geq x_n > 0 \) and \( m \geq 1 \) then

\[
x_1^m x_2 + x_2^m x_3 + \ldots + x_n^m \geq x_1 x_2^m + x_2 x_3^m + \ldots + x_n x_1^m.
\]

(2)

Suppose \( \lambda > \mu > 0 \), and put \( x_i = \frac{a_i^{2\mu}}{a_i^{2\mu}} \) and \( m = \lambda/\mu \). Then \( x_1 \geq x_2 \geq \ldots \geq x_n > 0 \) and \( m \geq 1 \), so (2) becomes

\[
\sum a_1^{2\lambda} a_2^{2\mu} \geq \sum a_1^{2\mu} a_2^{2\lambda}
\]

(3)

where the sums here and below are cyclic over \( a_1, a_2, \ldots, a_n \). Consequently, by (3) and the A.M.-G.M. inequality,

\[
\sum a_1^{2\lambda} a_2^{2\mu} \geq \sum \frac{a_1^{2\lambda} a_2^{2\mu} + a_2^{2\lambda} a_1^{2\mu}}{2} \geq (a_1 a_2)^{\lambda+\mu}.
\]

From the second inequality, equality in (1) implies that \( a_1 = a_2 = \ldots = a_n \).

If \( 0 > \lambda > \mu \) and \( a_1 \geq a_2 \geq \ldots \geq a_n > 0 \), then \( 0 < -\lambda < -\mu \) and

\[
a_n^{-1} \geq a_{n-1}^{-1} \geq \ldots \geq a_2^{-1} \geq a_1^{-1} > 0,
\]

so applying (1) we have
(a/\alpha_n^{-1}(\alpha_n^{-1})^{2(-\lambda)} + \ldots + (a/\alpha_n^{-1}(\alpha_n^{-1})^{2(-\lambda)} \geq (a/\alpha_n^{-1}(\alpha_n^{-1})^{\mu - \lambda} + \ldots + (a/\alpha_n^{-1}(\alpha_n^{-1})^{\mu - \lambda}

or

$$\alpha_n^{\mu/2} \alpha_n^{\lambda} + \ldots + \alpha_n^{\mu/2} \alpha_n^{\lambda} \geq (a/\alpha_n^{-1}(\alpha_n^{-1})^{\mu + \lambda} + \ldots + (a/\alpha_n^{-1}(\alpha_n^{-1})^{\mu + \lambda}$$

which is again (1).

II. Next we prove that if $x_1 \geq x_2 \geq \ldots \geq x_n > 0$ and $0 \leq \alpha \leq 1$, then the function

$$F(\alpha, n) = \sum x_1^{2-\alpha} x_2^{\alpha}$$

is a nonincreasing function of $\alpha$, that is,

$$F(\alpha_1, n) \geq F(\alpha_2, n) \quad \text{for} \quad 0 \leq \alpha_1 \leq \alpha_2 \leq 1.$$

Note that

$$F(\alpha, n) = \sum x_1^{2-\alpha} x_2^{\alpha},$$

and thus

$$F'(\alpha, n) = \frac{2}{x_1} \left( x_2^{\alpha} \ln \frac{x_2}{x_1} + x_2^{\alpha} \ln \frac{x_3}{x_2} + \ldots + x_n^{\alpha} \ln \frac{x_1}{x_n} \right),$$

and

$$F''(\alpha, n) = \frac{2}{x_1} \left( x_2^{\alpha} \ln^2 \frac{x_2}{x_1} + x_2^{\alpha} \ln^2 \frac{x_3}{x_2} + \ldots + x_n^{\alpha} \ln^2 \frac{x_1}{x_n} \right).$$

Since $F''(\alpha, n) \geq 0$, $F$ is convex. Thus we need only show that $F'(1, n) \leq 0$, that is,

$$x_1 x_2 \ln \frac{x_2}{x_1} + x_2 x_3 \ln \frac{x_3}{x_2} + \ldots + x_n x_1 \ln \frac{x_1}{x_n} \leq 0. \tag{4}$$

We do this by induction on $n$.

When $n = 3$, (4) is equivalent to

$$xy \ln \frac{y}{x} + yz \ln \frac{z}{y} + zx \ln \frac{x}{z} \leq 0 \quad \tag{5}$$

for $x \geq y \geq z > 0$. When $y = z$, the left side of (5) is just

$$xy \ln \frac{y}{x} + y^2 \ln 1 + yz \ln \frac{x}{y} = 0,$$

so we may assume $x \geq y > z > 0$. Moreover, since (5) is homogeneous in $x, y, z$, we can set $z = 1$. Inequality (5) then reduces to

$$xy \ln y - xy \ln x - y \ln y + x \ln x \leq 0,$$

or
and so we wish to prove that the function

\[ f(x) = \frac{x \ln x}{x - 1} \geq \frac{y \ln y}{y - 1}, \]

increases for \( x > 1 \). This can be done analytically. It also follows geometrically by rewriting \( f(x) \) as

\[ f(x) = \int \frac{1}{x} \cdot \frac{dt}{1 - \frac{1}{x}} \]

since the above expression gives the average height under the decreasing curve \( y = \frac{1}{t} \) for \( \frac{1}{x} \leq t \leq 1 \). (A similar method was used in [1980: 75].)

Now, assuming that \( F'(1,k) \leq 0 \) and noting that \( x_1 \geq x_k \geq x_{k+1} \), we have that

\[
F'(1,k+1) = F'(1,k) - x_k x_1 \ln \left( \frac{x_1}{x_k} \right) + x_k x_{k+1} \ln \left( \frac{x_{k+1}}{x_k} \right) + x_{k+1} x_1 \ln \left( \frac{x_1}{x_{k+1}} \right)
\]

\[
= F'(1,k) + \left( x_1 x_k \ln \left( \frac{x_k}{x_1} \right) + x_k x_{k+1} \ln \left( \frac{x_{k+1}}{x_k} \right) + x_{k+1} x_1 \ln \left( \frac{x_1}{x_{k+1}} \right) \right)
\]

\[
\leq 0 + 0 = 0
\]

by the induction hypothesis and (5). Thus \( F'(1,n) \leq 0 \) for all \( n \geq 3 \), and so \( F(a,n) \) is nonincreasing in \( a \). In particular, \( F(0,n) \geq F(a,n) \geq F(1,n) \), or

\[
\sum x_1^2 \geq \sum x_1^{2-\alpha} x_2^\alpha \geq \sum x_1 x_2
\]

(6)

for \( 0 \leq \alpha \leq 1 \).

Letting \( a_1 \geq a_2 \geq \ldots \geq a_n > 0 \) and \( \lambda > \mu > 0 \), we put

\[ x_i = a_i^{\lambda+\mu} \]

and

\[ \alpha = \frac{2\mu}{\lambda + \mu}; \]

then \( x_1 \geq x_2 \geq \ldots \geq x_n > 0 \) and \( 0 < \alpha < 1 \), and the second inequality of (6) reduces to (1).

If instead we assume \( a_1 \geq a_2 \geq \ldots \geq a_n > 0 \) and \( 0 > \lambda > \mu \), then we put

\[ x_i = a_i^{\lambda+\mu} \]

and

\[ \alpha = \frac{2\lambda}{\lambda + \mu}; \]
then again $x_1 \geq x_2 \geq \ldots \geq x_n > 0$ and $0 < \alpha < 1$, and (6) becomes

$$\sum_{n=1}^{\infty} a_n (\alpha + \mu) (2 - \frac{2\lambda}{\alpha + \mu}) \sum_{n=1}^{\infty} \frac{2\lambda}{\alpha + \mu} a_n \alpha^\lambda a_n \alpha^\mu$$

or

$$\sum_{n=1}^{\infty} a_n^2 \alpha^\mu a_n^\mu \geq (a_n a_n a_n a_n)^{\lambda + \mu},$$

which is (1) in this case as well.

III. For our final generalization we shall prove that if $x > y > z > 0$ and $t > 0$, then

$$x \left( \frac{y}{z} \right)^t + y \left( \frac{z}{x} \right)^t + z \left( \frac{x}{y} \right)^t \geq x + y + z.$$  \hfill (7)

Letting

$$H(t) = x \left( \frac{y}{z} \right)^t + y \left( \frac{z}{x} \right)^t + z \left( \frac{x}{y} \right)^t - x - y - z,$$

we have $H(0) = 0$, and so it is enough to prove that $H(t)$ is nondecreasing for $t > 0$. Then

$$H'(t) = x \left( \frac{y}{z} \right)^t \ln \left( \frac{y}{z} \right) + y \left( \frac{z}{x} \right)^t \ln \left( \frac{z}{x} \right) + z \left( \frac{x}{y} \right)^t \ln \left( \frac{x}{y} \right)$$

and

$$H''(t) = x \left( \frac{y}{z} \right)^t \ln^2 \left( \frac{y}{z} \right) + y \left( \frac{z}{x} \right)^t \ln^2 \left( \frac{z}{x} \right) + z \left( \frac{x}{y} \right)^t \ln^2 \left( \frac{x}{y} \right),$$

and since $H''(t) \geq 0$, $H$ is convex. Thus it suffices to show that $H'(0) \geq 0$, that is,

$$x \ln \left( \frac{y}{z} \right) + y \ln \left( \frac{z}{x} \right) + z \ln \left( \frac{x}{y} \right) \geq 0.$$  

As before, we can assume $x > y > z = 1$, and so we must prove

$$x \ln y - y \ln x + \ln x - \ln y \geq 0$$

or

$$\frac{\ln x}{x - 1} \leq \frac{\ln y}{y - 1}$$

for $x > y > 1$. This can be rewritten as

$$\int_1^x \frac{1}{t} \, dt \leq \int_1^y \frac{1}{t} \, dt$$

and so follows by another average height argument.

Now assume $a \geq b \geq c > 0$ and $\alpha \geq \mu$, $\lambda + \mu < 0$. Put

$$x = a^{-\lambda + \mu}, \quad y = b^{-(\lambda + \mu)}, \quad z = c^{-(\lambda + \mu)}$$

and

$$t = 1 - \frac{2\lambda}{\lambda + \mu}.$$
Then \( x \geq y \geq z > 0 \) and \( t \geq 0 \), so (7) implies that
\[
a^{-\lambda+\mu} \left( \frac{b}{c} \right)^{\lambda-\mu} + b^{-\lambda+\mu} \left( \frac{c}{a} \right)^{\lambda-\mu} + c^{-\lambda+\mu} \left( \frac{a}{b} \right)^{\lambda-\mu} \geq a^{-\lambda+\mu} + b^{-\lambda+\mu} + c^{-\lambda+\mu}.
\]
Multiplying by \((abc)^{\lambda+\mu}\), we obtain Murty's original inequality. If instead we assume \( a \geq b \geq c > 0 \) and \( \lambda \geq \mu, \lambda + \mu > 0 \), then we put
\[
x = c^{-\lambda+\mu}, \quad y = b^{-\lambda+\mu}, \quad z = a^{-\lambda+\mu}
\]
and
\[
t = 1 - \frac{2\mu}{\lambda + \mu}.
\]
Again, \( x \geq y \geq z > 0 \) and \( t \geq 0 \), and (7) implies Murty's inequality.

Proposed by George Tsintsifas, Thessaloniki, Greece.

(a) For all possible sets of \( n \) distinct points in a plane, let \( T(n) \) be the maximum number of equilateral triangles having their vertices among the \( n \) points. Evaluate \( T(n) \) explicitly in terms of \( n \), or (at least) find a good upper bound for \( T(n) \).

(b) If \( a_n = T(n)/n \), prove or disprove that the sequence \( \{a_n\} \) is monotonically increasing.

(c) Prove or disprove that \( \lim_{n \to \infty} a_n = \infty \).

I. Partial solution by Walther Janous, Ursulinengymnasium, Innsbruck, Austria.

(a) We limit ourselves to the triangular lattice formed with equilateral triangles, with \( n \) rows of points, the \( i \)th row having \( i \) points, as shown. Let \( t_n \) be the number of all possible equilateral triangles with vertices among these \( \binom{n+1}{2} \) lattice points. Then:
\[
t_1 = 0, \quad t_2 = 1, \quad t_3 = 5.
\]
Furthermore, we have the following recursion formula for \( t_n \):
This is equivalent to
\[ (t_n - 2t_{n-1} + t_{n-2}) - (t_{n-1} - 2t_{n-2} + t_{n-3}) = n - 1 \]  
(1)
or
\[ b_n - b_{n-1} = n - 1 \]  
(2)
where \( b_n = t_n - 2t_{n-1} + t_{n-2} \). Since \( b_3 = t_3 - 2t_2 + t_1 = 3 \), (2) implies that
\[ b_n = (n - 1) + \ldots + 4 + 3 + 3 = \left[ \frac{n}{2} \right] , \]
and so
\[ t_n - 2t_{n-1} + t_{n-2} = \left[ \frac{n}{2} \right] . \]
Now this can be written as
\[ c_n - c_{n-1} = \left[ \frac{n}{2} \right] \]
where \( c_n = t_n - t_{n-1} \). Also \( c_3 = t_3 - t_2 = 4 = \left[ \frac{3}{2} \right] + \left[ \frac{2}{2} \right] \), so
\[ c_n = \sum_{i=2}^{n} \left[ \frac{i}{2} \right] = \left[ \frac{n+1}{3} \right] . \]
Finally, we have
\[ t_n - t_{n-1} = \left[ \frac{n+1}{3} \right] \]
and \( t_3 = 5 = \left[ \frac{4}{3} \right] + \left[ \frac{3}{3} \right] \), so
\[ t_n = \sum_{i=3}^{n+1} \left[ \frac{i}{3} \right] = \left[ \frac{n+2}{4} \right] . \]
All the above were for \( n \geq 4 \), but we see that this final formula holds for \( n = 1, 2, 3 \) as well. Thus, if \( k = \left[ \frac{n+1}{2} \right] \),
\[ \frac{T(k)}{k^2} \geq \frac{\left[ \frac{n+2}{4} \right]}{\left[ \frac{n+1}{2} \right]^2} \approx \frac{1}{5} \]
so \( T(k) \) is of order at least \( k^2/6 \). (In particular, part (c) is true.)
II. Partial solution by Jordan B. Tabov, Sofia, Bulgaria.

[Editor's note: Tabov also found the formula \( t_n = \binom{n+2}{4} \) above, and thus that \( \lim_{n \to \infty} \frac{T(n)}{n^2} \geq \frac{1}{6} \).]

We shall now prove that

\[
\lim_{n \to \infty} \frac{T(n)}{n^2} \leq \frac{1}{3}.
\]

Given any \( n \) points, there are \( \binom{n}{2} \) segments connecting these points in pairs. Each of these segments may be a side of 2 equilateral triangles. Therefore \( T(n) \) cannot exceed \( \frac{2\binom{n}{2}}{3} = \frac{1}{3}n(n - 1) \).

A better lower bound for \( \lim_{n \to \infty} \frac{T(n)}{n^2} \) may be obtained by considering a hexagonal geoboard \( H \) formed by equilateral triangles as shown in the figure, with \( k \) lattice points on each side (including the endpoints). The total number of lattice points in \( H \) is \( 3k^2 + p(k) \), where \( p(k) \) is linear.

Let \( h(k) \) be the number of equilateral triangles with vertices among the points of \( H \). The number of such triangles with 2 or 3 vertices on the outer ring of \( H \) is a polynomial of degree 2 in \( k \), and the number with no vertices on the outer ring is of course \( h(k - 1) \). The number of equilateral triangles with exactly one vertex on the outer ring works out to be \( 7k^3 + \) a polynomial of degree 2. Thus

\[
h(k) = h(k - 1) + 7k^3 + q(k),
\]

where \( q(k) \) is a polynomial of degree 2, and so

\[
h(k) = 7 \sum_{i=1}^{k} i^3 + a \text{ polynomial of degree 3}
= \frac{7}{4}k^4 + a \text{ polynomial of degree 3}.
\]

Hence

\[
\lim_{n \to \infty} \frac{T(n)}{n^2} \geq \lim_{n \to \infty} \frac{\frac{7}{4}k^4}{(3k^2)^2} = \frac{7}{36}.
\]

This result and the result obtained from triangular geoboards lead me to formulate the following
Conjecture: $\lim_{n \to \infty} \frac{T(n)}{n^2} = \frac{1}{5}$.

(since $\frac{1}{5} = \frac{1}{5} + \frac{1}{6} + \frac{1}{6^2} + \frac{1}{6^3} + \ldots$).

III. Comment by the Editor.

This problem is by no means answered and quite a few questions remain.

(1) Does $\lim_{n \to \infty} \frac{T(n)}{n^2}$ exist? If so, what is it?

(2) What configuration of $n$ points yields the maximum number of equilateral triangles?

(3) What is the answer to part (b) of the original problem?

(4) Two solvers independently found, using different proofs, that the triangular grid with $n$ points on each side has exactly $\frac{n+2}{4}$ equilateral triangles. Is there a natural correspondence between such triangles and the four-element subsets of an $(n+2)$-element set?

Part (c) was also answered by FRIEND H. KIERSTEAD JR., Cuyahoga Falls, Ohio.

Both figures are arrangements of the same 16 arbitrary numbers $A,B,C,\ldots,P$, and both have $A$ in the upper left corner cell. Enumerate all the ways the arbitrary $A,B,C,\ldots,P$ can be arranged to form pandiagonal magic squares in which $A$ is fixed as shown.

Solution by the proposer.

From Crux 605 [1982: 22] it follows that every pandiagonal fourth-order magic square is composed of 8 disjoint pairs of numbers, each of which sums to half the magic sum, and that these 8 pairs can be written and situated as follows:
By (1) and (3), which with (1), gives

\[ s + t - x - y = 0 \]  \hspace{1cm}  \hspace{1cm}  (1)  \\
\[ u + v + w - z = 0 \]  \hspace{1cm}  \hspace{1cm}  (2)  \\
\[ s - t - w - z = 0 \]  \hspace{1cm}  \hspace{1cm}  (3)  \\
\[ u - v + x - y = 0 \]  \hspace{1cm}  \hspace{1cm}  (4)

By (1) and (3),

\[ s = \frac{1}{2}(w + x + y + z) \]

which, with (1), gives

\[ t = \frac{1}{2}(w - x - y + z). \]

By (2) and (4),

\[ u = \frac{1}{2}(w + x - y - z) \]
\[ v = \frac{1}{2}(w - x + y - z). \]

These last four equations show that every cell in (*) can be expressed in terms of \( f, w, x, y, z \).

In particular, the cell in the upper left corner equals

\[ f + \frac{1}{2}(w + x + y + z) \]

whose value does not change if \( w, x, y, z \) are permuted in any of the 24 possible ways. Moreover we find that

\[ f + t = f + s - (w + z) \]
\[ f - t = f + s - (x + y) \]
\[ f + u = f + s - (w + x) \]
\[ f - u = f + s - (y + z) \]
\[ f + v = f + s - (w + y) \]
\[ f - v = f + s - (x + z) \]

and thus permuting \( w, x, y, z \) will not change the values of the entries in (*), only their position. Note that \((f + t) + (f - t)\), for example, is unchanged by such a permutation, so the resulting array will still be in the
There are in fact exactly 24 such magic squares. This follows from Frenicle’s 1693 enumeration of all (essentially different) fourth-order magic squares on the integers 1, 2, 3, ..., 16. He counted only those squares with the properties that

(i) the smallest of the four corner cells occurs in the upper left corner, and

(ii) of the two cells rookwise adjacent to the upper left corner cell, the cell in the top row is the smaller.

These two properties ensure that rotations and reflections are not counted as different. The resulting 880 magic squares are displayed and categorized on pp. 188-198 of W.H. Benson and O. Jacoby, New Recreations with Magic Squares, Dover, 1976. Of these, 48 turn out to be pandiagonal (type I in Benson and Jacoby’s list), with 12 having 1 in the upper left corner. Since we do not wish property (ii) above, we double this figure, arriving at the same 24 magic squares (and only those) found earlier.

* * *

Let $ABC$ be a triangle with incentre $I$. Prove that the Euler lines of triangles $IBC$, $ICA$, $IAB$, and $ABC$ are all concurrent.

Let $\Gamma$ be the circumcircle of $\Delta ABC$, with center $O$ and radius $R$, and let $r$ be the radius of the incircle of $\Delta ABC$. Let $G$ be the median point, so that $GO$ is the Euler line of $\Delta ABC$. Let $D$ be the intersection of $AI$ with $\Gamma$, that is, the midpoint of arc $BC$. Then it is well-known (e.g. Theorem 292, page 185 of R.A. Johnson’s Advanced Euclidean Geometry) that $D$ is the center of a circle passing through $B$, $I$, and $C$. This means that $D$ is the circumcenter of
\[ \Delta BIC, \text{ so that} \]
\[ \quad CD = ID. \quad (1) \]

Let \( G_1 \) be the median point of \( \Delta BIC \), so that \( DG_1 \) is the Euler line of this triangle.

Let \( O_1 \) be the midpoint of \( BC \). Then since \( G \) and \( G_1 \) are median points,
\[
\frac{AG}{GO_1} = \frac{IG_1}{G_1O_1} = 2.
\]

Thus \( GG_1 \parallel AI \), and hence, letting \( E \) be the intersection of \( GG_1 \) and \( OD \),
\[
\frac{GG_1}{G_1E} = \frac{AT}{TD} \quad (2)
\]
and
\[
DE = \frac{2}{3} DO_1. \quad (3)
\]

It also follows that the Euler line \( DG_1 \) of \( \Delta BIC \) will intersect the Euler line \( GO \) of \( \Delta ABC \) between \( G \) and \( O \). We let \( S \) be the point of intersection.

Let \( F \) be the foot of the perpendicular from \( I \) to \( AB \). Since \( \angle BAD = \angle BCD \), \( \Delta AFI \sim \Delta CO_1D \), and hence
\[
\frac{TA}{CD} = \frac{FI}{O_1D} = \frac{r}{O_1D} \quad (4)
\]

Applying the theorem of Menelaus to the triangle \( GOE \) with the transversal \( SG_1D \), we have
\[
1 = \frac{GS}{OS} \cdot \frac{OD}{ED} \cdot \frac{EG_1}{GG_1}
= \frac{GS}{OS} \cdot \frac{OD}{ED} \cdot \frac{TD}{AT} \quad \text{by (2)}
= \frac{GS}{OS} \cdot \frac{OD}{ED} \cdot \frac{CD}{AT} \quad \text{by (1)}
= \frac{GS}{OS} \cdot \frac{R}{\frac{2}{3} DO_1} \cdot \frac{CD}{AT} \quad \text{by (3)}
= \frac{GS}{OS} \cdot \frac{3R}{2DO_1} \cdot \frac{r}{r} \quad \text{by (4)}
= \frac{GS}{OS} \frac{3R}{2r},
\]
that is,
\[
\frac{GS}{OS} = \frac{2r}{3R}.
\]

Now if we consider the Euler lines of \( \Delta AIB \) or \( \Delta CIA \) rather than \( \Delta BIC \), we will
arrive at the same ratio; thus the Euler lines of \( \triangle AIB \), \( \triangle CIA \), and \( \triangle BIC \) all intersect the Euler line of \( \triangle ABC \) in the same point \( S \) (we call this point the Schiffler point of \( \triangle ABC \)).

Also solved by D.J. SMEENK, Zaltbommel, The Netherlands.

Determine the largest constant \( k \) such that the inequality

\[
x \leq k \sin x + (1 - k) \tan x
\]

holds for all \( k \leq x \leq 0, x \leq \pi/2 \).

(The inequality obtained when \( k \) is replaced by 2/3 is the Snell-Huygens inequality, which is fully discussed in Problem 115 [1976: 98-99, 111-113, 137-133].)

Solution by Richard I. Hess, Rancho Palos Verdes, California.

Let

\[
f(x) = k \sin x + (1 - k) \tan x - x
\]

and suppose \( k = \frac{2}{3} + \epsilon \). Then for \( x \ll 1 \),

\[
\sin x = x - \frac{x^3}{6} + O(x^5)
\]

\[
\tan x = x + \frac{x^3}{3} + O(x^5)
\]

and so

\[
f(x) = \left(\frac{2}{3} + \epsilon\right)(x - \frac{x^3}{6} + O(x^5)) + \left(\frac{1}{3} - \epsilon\right)(x + \frac{x^3}{3} + O(x^5)) - x
\]

\[
= -\frac{\epsilon x^3}{6} - \frac{\epsilon x^3}{3} + O(x^5)
\]

\[
= -\frac{\epsilon x^3}{2} + O(x^5).
\]

For suitably small \( x \) this must be negative for \( \epsilon > 0 \), so the given inequality won't hold unless \( \epsilon \leq 0 \). Thus the largest value of \( k \) is \( \frac{2}{3} \).

Also solved by WALTHER JANOUS, Ursulinengymnasium, Innsbruck, Austria; FRIEND H. KIERSTEAD JR., Cuyahoga Falls, Ohio; M.S. KLAMKIN, University of Alberta, Edmonton, Alberta; EDWIN M. KLEIN, University of Wisconsin, Whitewater, Wisconsin; KEE-WAI LAU, Hong Kong; JORDAN B. TABOV, Sofia, Bulgaria; A. TAMANAS, Thornton Heath, Surrey, England; and the proposers.

Solve, for $x \in [0,2\pi)$, the equation

$$176\cos x + 64\sin x = 75\cos 2x + 80\sin 2x + 101.$$ 

Solution by Edwin M. Klein, University of Wisconsin, Whitewater, Wisconsin.

Clearly $x \neq \pi$, so using the substitution $t = \tan(x/2)$ we have

$$\sin x = \frac{2t}{1 + t^2}, \quad \cos x = \frac{1 - t^2}{1 + t^2}$$

and thus

$$\sin 2x = 2\sin x \cos x = \frac{4t(1 - t^2)}{(1 + t^2)^2}$$

$$\cos 2x = 1 - 2\sin^2 x = \frac{1 - 6t^2 + t^4}{(1 + t^2)^2}.$$ 

The given equation then simplifies to

$$176(1 - t^4) + 128t(1 + t^2) = 75(1 - 6t^2 + t^4) + 320t(1 - t^2) + 101(1 + t^2)^2$$

or

$$352t^4 - 448t^3 - 248t^2 + 192t = 0$$

or

$$8t(2t - 1)(2t - 3)(8t + 8) = 0.$$ 

Hence, $\tan(x/2) = 0$, $1/2$, $3/2$, $-8/11$ and so the solutions are

$$x = 2\arctan 0 = 0$$

$$x = 2\arctan 1/2 \approx 53.13^\circ$$

$$x = 2\arctan 3/2 \approx 112.62^\circ$$

$$x = 2\pi - 2\arctan 8/11 \approx 287.95^\circ.$$ 

Also solved by HAYO AHLBURG, Benidorm, Alicante, Spain; SAM BAETHGE, San Antonio, Texas; FRIEND H. KIERSTEAD JR., Cuyahoga Falls, Ohio; KEE-WAI LAU, Hong Kong; J.A. McCALLUM, Medicine Hat, Alberta; STANLEY RABINOWITZ, Digital Equipment Corp., Nashua, New Hampshire; D.J. SMEENK, Zaltbommel, The Netherlands; and the proposer. Found by J.T. GROENMAN, Arnhem, The Netherlands; RICHARD I. HESS, Rancho Palos Verdes, California; J.A. McCALLUM, Medicine Hat, Alberta; GLEN E. MILLS, Valencia Community College, Orlando, Florida; and the proposer. There was one incorrect solution submitted. The proposer notes that the word jean, as in jeans, comes from the word Genoa (Gênes in French) where this fabric was produced and exported. Leroy F. Meyers is reminded of the homophonous verse

Gal, amant de la reine, alla, tour magnanime,

Galamment de l’Arènes à la Tour Magne, à Nîmes.

* * *

Show that, for $n = 1, 2, 3, \ldots$,

\[
\sum_{k=1}^{n} \arctan \frac{2}{k^2} = \frac{3\pi}{4} - \arctan \frac{1}{n} - \arctan \frac{1}{n + 1}.
\]

Solution by M. Parmenter, Memorial University of Newfoundland, St. John’s, Newfoundland.

We will prove this by induction.

When $n = 1$, the equation to be proved reads

\[
\arctan 2 = \frac{3\pi}{4} - \frac{\pi}{4} - \arctan \frac{1}{2}.
\]

This is correct since \(\arctan 2 + \arctan \frac{1}{2} = \frac{\pi}{2}\).

Assume the equation for $n = s$. Then when $n = s + 1$, the left side of the above equation is

\[
\sum_{k=1}^{s+1} \arctan \frac{2}{k^2} = \sum_{k=1}^{s} \arctan \frac{2}{k^2} + \arctan \frac{2}{(s + 1)^2} = \frac{3\pi}{4} - \arctan \frac{1}{s} - \arctan \frac{1}{s+1} + \arctan \frac{2}{(s + 1)^2}.
\]

We wish to prove this is equal to

\[
\frac{3\pi}{4} - \arctan \frac{1}{s + 1} - \arctan \frac{1}{s + 2},
\]

that is, we have to prove
\[
\frac{2}{(s + 1)^2} = \arctan \frac{1}{s} - \arctan \frac{1}{s + 2}.
\]

But these are all first quadrant angles and
\[
\tan \left( \arctan \frac{1}{s} - \arctan \frac{1}{s + 2} \right) = \frac{\frac{1}{s} - \frac{1}{s + 2}}{1 + \frac{1}{s(s + 2)}} = \frac{2}{s(s + 2) + 1} = \frac{2}{(s + 1)^2},
\]
as required.

KLAMKIN, "On some inverse tangent summations", Fibonacci Quart. 14 (1976) 385-388.

Prove that an odd number which is a perfect square cannot be perfect.

I. Solution by Frank P. Battles and Laura L. Kelleher, Massachusetts Maritime Academy, Buzzards Bay, Massachusetts.

If a number is perfect the sum of its divisors is twice the number itself and hence this sum is even. Consider a number which is an odd perfect square. Since it is odd, all of its divisors are odd. Since it is a perfect square, it has an odd number of divisors. It follows that the sum of its divisors is odd, and hence this number is not a perfect number.

II. Solution by Edwin M. Klein, University of Wisconsin, Whitewater, Wisconsin.

More generally, if \( n \) is a perfect square or twice a perfect square, then \( n \) is not perfect, because \( \sigma(n) \) is odd (cf. David M. Burton, Elementary Number Theory, p.118 ex. 7(b) and p.224 ex. 2(b)).
Also solved by SAM BAETHGE, San Antonio, Texas; RICHARD I. HESS, Rancho Palos Verdes, California; WALThER JANOUS, Ursulinengymnasium, Innsbruck, Austria; FRIEND H. KIERSTEAD JR., Cuyahoga Falls, Ohio; M.S. KLAMKIN, University of Alberta, Edmonton, Alberta; KEE-WAI LAU, Hong Kong; LEROY F. WANG, Wilfrid Laurier University, Waterloo, Ontario; KENNETH M. WILKE, Topeka, Kansas; and the proposer. Priellipp and Wagon used the known result that any odd perfect number is of the form $p^m q^2$ where $p$ is a prime and $p$ and $q$ are both congruent to 1 mod 4 (e.g. see p.128 of Beck, Bleicher, and Crowe, Excursions into Mathematics). Meyers suspects that no perfect $k^{th}$ power ($k > 1$) is a perfect number; any comments from out there?

* * *

A paper square $ABCD$ is folded so that vertex $C$ falls on $AB$ and side $CD$ is divided into two segments of lengths $l$ and $m$, as shown in the figure. Find the minimum value of the ratio $l/m$.

I. Solution by Sam Baethge, San Antonio, Texas.

Without loss of generality let $AB = 1$ and label the figure as shown by using the similar right triangles.

Then

$$\frac{xm}{\sqrt{\ell^2 - x^2}} + \frac{l\ell}{\sqrt{\ell^2 - x^2}} + \sqrt{\ell^2 - x^2} = 1.$$ 

Since $m + l = 1$, $l/m$ is minimized when $l$ is minimized. Thus we substitute for $m$ and solve for $l$, yielding

$$(x + l)(1 - l) + (l^2 - x^2) = \sqrt{\ell^2 - x^2}$$

$$(l + x)(1 - l + \ell - x) = \sqrt{\ell^2 - x^2}$$

$$(l + x)^2(1 - x)^2 = \ell^2 - x^2$$

$$(l + x)(1 - x)^2 = l - x$$

$$\ell[(1 - x)^2 - 1] = -x - x(1 - x)^2$$

$$\ell = \frac{x[1 + (1 - x)^2]}{2x - x^2} = \frac{x^2 - 2x + 2}{2 - x} = -x + \frac{2}{2 - x}.$$
Then

\[ \frac{d\ell}{dx} = -1 + \frac{2}{(x - 2)^2} . \]

For \( \frac{d\ell}{dx} = 0 \), \( (x - 2)^2 = 2 \) or \( x = 2 - \sqrt{2} \). Then \( \ell = 2\sqrt{2} - 2 \) and \( m = 3 - 2\sqrt{2} \), and so

\[ \frac{\ell}{m} = \frac{2\sqrt{2} - 2}{3 - 2\sqrt{2}} = \frac{(2\sqrt{2} - 2)(3 + 2\sqrt{2})}{3 - 2\sqrt{2}} = 2\sqrt{2} + 2. \]

Note that the minimum occurs when the acute angles at \( C \) are each \( 45^\circ \).

II. Solution by Dan Sokolowsky, Brooklyn, N.Y.

Let \( E \) denote the point dividing \( CD \) into segments of length \( \ell \) and \( m \). By problem 995 of this journal ([1984: 319], solution [1986: 58]) the inradius of \( \Delta CAE \) has length \( m = DE \), so

\[ \frac{\ell}{m} = \frac{\text{hypotenuse of } \Delta CAE}{\text{inradius of } \Delta CAE}. \]

This ratio is the same for similar triangles. We therefore lose no generality in confining ourselves to the set \( \mathcal{J}_1 \) of all right triangles which have common inradius 1, in which case the stated problem is equivalent to the following:

[1] Minimize the hypotenuse \( h \) over all triangles in \( \mathcal{J}_1 \).

Let \( \Delta = \Delta CAE \in \mathcal{J}_1 \) and let \( I \) denote its incenter. Then

\[ \angle CIE = 180^\circ - (\angle ICE + \angle IEC) \]
\[ = 180^\circ - \frac{1}{2}(\angle IAC + \angle IAE) \]
\[ = 180^\circ - 45^\circ \]
\[ = 135^\circ , \]
and thus [1] is equivalent to a special case of

[2] Given \( \ell PIQ \) and a circular arc \( K \) from \( PI \) to \( QI \) with radius 1 and center \( I \), let \( CE \) be a tangent to \( K \) with \( C \) on \( IP \) and \( E \) on \( IQ \). Determine the minimum length of \( CE \).

It is well known that \( CE \) is minimum when it meets \( IP \) and \( IQ \) at equal angles \( \alpha = (180^\circ - \ell PIQ)/2 \), and thus

\[ \min CE = 2\cot \alpha . \]

In the special case of our problem, \( \alpha = \frac{1}{2}(180^\circ - 135^\circ) = 221^\circ \). Hence

\[ \min \frac{\ell}{m} = 2\cot \frac{221^\circ}{2} = 2(\sqrt{2} + 1) . \]
III. Comment by the proposer.

Most of my mathematics revolves around my ten-year hobby of origami. A consequence of the above corner-to-edge folding of a square is a method of rapid folding of a square into thirds, fifths, sevenths, and beyond. Labeling the figure as shown, we can obtain
\[ y = \frac{2x}{1 + x}, \]
and therefore, for example:
- if \( x = \frac{1}{2} \) (easily found), then \( y = \frac{2}{3} \), so \( y \) folded in half yields one edge folded into thirds.
- if \( x = \frac{1}{4} \) (easily found), then \( y = \frac{2}{5} \), which produces an edge folded into fifths.
- if \( x = \frac{3}{4} \) then \( y = \frac{6}{7} \), which produces an edge folded into sevenths.

This method was discovered by Koji Fushimi and was reported in the *British Origami Magazine* 95 (August 1982) p.20, with the comment that it was the easiest and best method known for achieving thirds and fifths. For another construction, see "Mathematics of origami" by Jacques Justin, in 115 (December 1985) pp.18-20 of the same magazine.

* *

\( D, E, \) and \( F \) are points on sides \( BC, CA, \) and \( AB, \) respectively, of triangle \( ABC, \) and \( AD, BE, \) and \( CF \) concur at point \( H. \) If \( H \) is the incenter of triangle \( DEF, \) prove that \( H \) is the orthocenter of triangle \( ABC. \)
I. Solution by Jordi Dou, Barcelona, Spain.

Let $M$ be the intersection of $ED$ and $CH$.

In the complete quadrilateral with edges $CE$, $EH$, $HD$, and $DC$, $M$ and $F$ divide $CH$ harmonically, that is, $(CH,MF) = -1$ (e.g. Theorem 2.8.10, page 85 of [1]). Thus (e.g. Theorem 2.5.7, page 75 of [1]), the cross ratio $D(CA,EF)$ must also be $-1$. That is,

$$\frac{\sin CDE}{\sin CDA} = \frac{\sin CDF}{\sin FDA} = -1.$$ 

But $DA$ bisects $\angle EDF$, so $\sin FDA = -\sin EDA$. Thus

$$\sin CDF = \sin CDF = \sin FDB,$$

which implies that $DC$ is perpendicular to $DA$. Therefore $AD$ and similarly $BE$ and $CF$ are altitudes of $\triangle ABC$, that is, $H$ is the orthocenter of $\triangle ABC$.

Reference:

We use normal homogeneous trilinear coordinates with respect to $\triangle DEF$. We obtain $D = (1,0,0)$, $E = (0,1,0)$, $F = (0,0,1)$, $H = (1,1,1)$. Thus

- $HD$ is the line $y = z$, so $A = (a_1,a_2,a_2)$
- $HE$ is the line $x = z$, so $B = (b_1,b_1,b_2)$
- $HF$ is the line $x = y$, so $C = (c_2,c_2,c_1)$.

Also, $B$, $D$, $C$ are collinear, and thus we get

$$\begin{vmatrix} b_2 & b_1 & b_2 \\ 1 & 0 & 0 \\ c_2 & c_2 & c_1 \end{vmatrix} = 0$$

or

$$b_1c_1 = b_2c_2.$$

In the same way,

$$c_1a_1 = c_2a_2$$

and

$$a_1b_1 = a_2b_2.$$ 

Hence

$$\frac{b_1}{b_2} = \frac{c_2}{c_1} = \frac{a_1}{a_2} = \frac{b_2}{b_1},$$

whence $b_1^2 = b_2^2$. Since $b_1 = b_2$ would give $B = (1,1,1) = H$, we must have
160

\[ b_1 = -b_2 \text{ and hence } B = (1, -1, 1). \] This means that \( B \) (and similarly \( A \) and \( C \)) is an excenter of \( \triangle DEF \). It follows that \( AC, BC, \) and \( AB \) are the exterior angle-bisectors of \( \triangle DEF \), and thus are perpendicular to \( BE, AD, \) and \( CF \) respectively. Therefore \( AD, BE, CF \) are the altitudes of \( \triangle ABC \) and \( H \) is the orthocenter of this triangle.

Also solved by R.H. EDDY, Memorial University of Newfoundland, St. John’s, Newfoundland; WALTHER JANOUS, Ursulinengymnasium, Innsbruck, Austria; DAN SOKOLOWSKY, Brooklyn, N.Y.; and the proposer.

\[ \star \quad \star \quad \star \]

Determine all quadruples \((a, b, c, d)\) of nonzero integers satisfying the Diophantine equation

\[ abcd\left[\frac{1}{a} + \frac{1}{b} + \frac{1}{c} + \frac{1}{d}\right]^2 = (a + b + c + d)^2 \]

and such that \(a^2 + b^2 + c^2 + d^2\) is a prime.

Solution par C. Festraets-Hamoir, Bruxelles, Belgique.

\[ abcd\left[\frac{1}{a} + \frac{1}{b} + \frac{1}{c} + \frac{1}{d}\right]^2 = (a + b + c + d)^2 \]

\[ \iff abcd\left[\frac{1}{a^2} + \frac{1}{b^2} + \frac{1}{c^2} + \frac{1}{d^2} + \frac{2}{ab} + \frac{2}{ac} + \frac{2}{ad} + \frac{2}{bc} + \frac{2}{bd} + \frac{2}{cd}\right] \]

\[ = a^2 + b^2 + c^2 + d^2 + 2ab + 2ac + 2ad + 2bc + 2bd + 2cd \]

\[ \iff \frac{bcd}{a} + \frac{acd}{b} + \frac{abd}{c} + \frac{abc}{d} = a^2 + b^2 + c^2 + d^2 \]

\[ \iff b^2c^2d^2 + a^2c^2d^2 + a^2b^2d^2 + a^2b^2c^2 = abcd(a^2 + b^2 + c^2 + d^2). \]

Posons \(a^2 + b^2 + c^2 + d^2 = p\) (\(p\) premier). On a

\[ b^2c^2d^2 + a^2c^2d^2 + a^2b^2d^2 + a^2b^2c^2 \equiv 0 \pmod{p} \]

\[ b^2c^2(d^2 + a^2) + a^2d^2(c^2 + b^2) \equiv 0 \pmod{p} \]

\[ b^2c^2(-b^2 - c^2) + a^2d^2(c^2 + b^2) \equiv 0 \pmod{p} \]

\[ (a^2d^2 - b^2c^2)(b^2 + c^2) \equiv 0 \pmod{p} \]

\[ a^2d^2 - b^2c^2 \equiv 0 \pmod{p} \quad \text{car} \quad (b^2 + c^2, p) = 1. \]

De même, on a

\[ a^2c^2 - b^2d^2 \equiv 0 \pmod{p}. \]

D'où, par addition

\[ a^2d^2 - b^2c^2 + a^2c^2 - b^2d^2 \equiv 0 \pmod{p} \]

\[ (a^2 - b^2)(d^2 + c^2) \equiv 0 \pmod{p} \]

\[ a^2 - b^2 \equiv 0 \pmod{p} \quad \text{car} \quad (d^2 + c^2, p) = 1. \]
Par symétrie, on obtient

\[ a^2 \equiv b^2 \equiv c^2 \equiv d^2 \pmod{p} \]
\[ p = a^2 + b^2 + c^2 + d^2 \equiv 4a^2 \pmod{p}, \]
\[ a^2 = 0 \quad \text{ou} \quad a^2 = p \]

ce qui est impossible. Donc, il n'existe aucun quadruple d'entiers positifs non nuls \((a, b, c, d)\) satisfaisant les conditions données.

Also solved by FRIEND H. KIERSTEAD JR., Cuyahoga Falls, Ohio; and the proposer.
